Background:	This gene encodes a type II transmembrane glycoprotein belonging to the M28 peptidase family. The protein acts as a glutamate carboxypeptidase on different alternative substrates, including the nutrient folate and the neuropeptide N-acetyl-I-aspartyl-I-glutamate and is expressed in a number of tissues such as prostate, central and peripheral nervous system and kidney. A mutation in this gene may be associated with impaired intestinal absorption of dietary folates, resulting in low blood folate levels and consequent hyperhomocysteinemia. Expression of this protein in the brain may be involved in a number of pathological conditions associated with glutamate excitotoxicity. In the prostate the protein is up- regulated in cancerous cells and is used as an effective diagnostic and prognostic indicator of prostate cancer. This gene likely arose from a duplication event of a nearby chromosomal

region. Alternative splicing gives rise to multiple transcript variants encoding several different

HEK293T cells were transfected with the pCMV6-ENTRY control (Left lane) or pCMV6-ENTRY FOLH1 ([RC218310], Right lane) cDNA for 48 hrs and lysed. Equivalent amounts of cell lysates (5 ug per lane) were separated by SDS-PAGE and immunoblotted with anti-FOLH1. Positive lysates [LY429203] (100ug) and [LC429203] (20ug) can be purchased separately from OriGene.

HEK293T cells transfected with either [RC218310] overexpress plasmid (Red) or empty vector control plasmid (Blue) were immunostained by anti-FOLH1 antibody (TA504568), and then analyzed by flow cytometry.
